The dispersion curves can be obtained by solving the Rayleigh–Lamb frequency equation $\omega^2 = [25] - \omega^2$. Define $\delta c^2 S = c^2 P^2 - 2$, $\delta c^2 S = c^2 L^2 - 2$, $k L \omega = c L$, $q \delta k^2 L^2 k^2 P^2 - 2$, $s \delta k^2 L^2 k^2 S^2 - 2$, where c_P is the pressure (longitudinal motion) wave velocity, c_S is the shear (transverse motion) wave v ...

Rayleigh waves are a type of surface acoustic wave that travel along the surface of solids. They can be produced in materials in many ways, such as by a localized impact or by piezo-electric transduction, and are frequently used in non-destructive testing for detecting defects. Rayleigh waves are part of the seismic waves that are produced on the Earth by earthquakes. When guided in layers they are referred to as Lamb waves, Rayleigh–Lamb waves, or generalized Rayleigh waves.

The term Rayleigh–Lamb waves embraces the Rayleigh wave, a type of wave that propagates along a single surface. Both Rayleigh and Lamb waves are constrained by the elastic properties of the surface(s) that guide them. Abstract A nondestructive technique is described for the measurement of elastic constants of isotropic plates using ultrasonic Rayleigh–Lamb waves. The experimental method employs continuous harmonic waves and a pair of variable-angle contact transducers in pitch-catch mode.

Abstract. The antecedent work on Lamb waves is not hard to identify. It was Lord Rayleigh in 1889 who first explained wave propagation along a guided surface [1], and the waves are known as Rayleigh waves today. Following Rayleigh ' s work, Horace Lamb, a British applied mathematician, reported the waves discovered in plates in one of his historic publications, On Waves in an Elastic Plate, in 1917 [2], and the waves were named after him as Lamb waves.
