Scalability Of Openfoam For Simulations Of A Novel

OpenFOAM (see [7]) is an open source Computational Fluid Dynamics (CFD) toolbox, (see [29]). It is useful to simulate complex fluid flows involving turbulence, heat transfer and solid dynamics. It is a generic CFD software package with many tools for several main tasks of the simulation such as pre-processing (meshing),

Scalability Of Openfoam For Simulations Of A Novel

Compressible density-based solvers are widely used in OpenFOAM, and the parallel scalability of these solvers is crucial for large-scale simulations. In this paper, we report our experiences with the scalability of OpenFOAM's native rhoCentralFoam solver, and by making a small number of modifications to it, we show the degree to which the scalability of the solver can be improved.

About OpenCFD. OpenCFD Ltd has been managing and developing OpenFOAM since its debut in 2004, releasing all versions prior to 8th August 2011, when OpenCFD transferred the IP rights to the US foundation "OpenFOAM Foundation, inc." After that date OpenCFD Ltd. continued to manage and develop OpenFOAM, preparing all releases whose IP was later transferred to and released by OpenFOAM Foundation ...

Each process in an OpenFOAM parallel simulation writes one file for each output field at each output time: number of files = number of output fields x number of output times x number of processes. which can quickly lead to large numbers of small files. Some users of OpenFOAM on ARCHER have produced millions of files in the course of a project.

OpenFOAM simulations around return-to-office safe distancing demonstrate the effect of occupant proximity, ventilation systems and contamination avoidance unique to each office and plant environment. This example in an enclosed space demonstrates that the ventilation air-curtain can be protective, or disturbed, by an extreme respiratory event.

In terms of parallel scalability, OpenFOAM, scales very well from 8 to 512 CPUs, but the intranode scalability from 1 to 8 CPUs is quite poor (interestingly, this is also the case for Semtex, although it is a little better, 4.4 vs 2.4 see Tables 6 and 7). An optimum parallel efficiency of 46.8% is achieved with OpenFOAM when using 128 CPUs and the optimum number of grid nodes per CPU is found to be 32,000.
